

The Formal Definition of a Limit

by Sophia

WHAT'S COVERED

In this lesson, you will establish a relationship between ϵ and δ to formally prove the value of a limit. Specifically, this lesson will cover:

1. The Formal Definition of a Limit
2. Proving Limits (Finding δ in Terms of ϵ)

1. The Formal Definition of a Limit

This process is much like what we did in the last challenge, except this time we will have symbols instead of numbers. Since this process is more complicated with nonlinear functions, we will be focusing on linear functions only.

The formal definition of a limit is as follows:

CONCEPT TO KNOW

$\lim_{x \rightarrow a} f(x) = L$ means for every given $\epsilon > 0$, there is a $\delta > 0$ so that if x is within δ units of a (and $x \neq a$), then $f(x)$ is within ϵ units of L .

Equivalently, we can say $|f(x) - L| < \epsilon$ whenever $0 < |x - a| < \delta$.

HINT

The use of the lower case Greek letters ϵ (epsilon) and δ (delta) in the definition is standard, and this definition is sometimes called the "epsilon-delta" definition of limit.

2. Proving Limits (Finding δ in Terms of ϵ)

In order to prove a limit, we need to accomplish the following:

- Find an expression for δ in terms of ϵ , starting with $|f(x) - L| < \epsilon$.
- For the expression you found, show that $0 < |x - a| < \delta$ leads to $|f(x) - L| < \epsilon$.

🔗 **EXAMPLE** Prove the limit: $\lim_{x \rightarrow 4} (2x - 1) = 7$

Start with $|2x - 1 - 7| < \varepsilon$. Then, convert to an inequality with $x - 4$ in the middle (just as before).

$$\begin{aligned}
 |2x - 8| &< \varepsilon && \text{Simplify the expression.} \\
 -\varepsilon &< 2x - 8 < \varepsilon && |x| < a \text{ means } -a < x < a. \\
 -\varepsilon + 8 &< 2x < \varepsilon + 8 && \text{Add 8 to all parts.} \\
 -\frac{\varepsilon}{2} + 4 &< x < \frac{\varepsilon}{2} + 4 && \text{Divide all parts by 2.} \\
 -\frac{\varepsilon}{2} &< x - 4 < \frac{\varepsilon}{2} && \text{Subtract 4 from all parts to get } x - 4 \text{ in the middle.}
 \end{aligned}$$

Thus, it appears that $\delta = \frac{\varepsilon}{2}$. Note also that the last inequality can be written $|x - 4| < \frac{\varepsilon}{2}$.

Now, to prove the limit, we basically just reverse the steps we did. While this is redundant, it is important since we need to establish that $-\frac{\varepsilon}{2} < x - 4 < \frac{\varepsilon}{2}$ directly leads to a statement that $f(x)$ is within ε units of 7.

The goal is to convert this into an inequality with $2x - 1$ in the middle.

Start with $-\frac{\varepsilon}{2} < x - 4 < \frac{\varepsilon}{2}$.

$$\begin{aligned}
 -\frac{\varepsilon}{2} + 4 &< x < \frac{\varepsilon}{2} + 4 && \text{Add 4 to all parts.} \\
 -\varepsilon + 8 &< 2x < \varepsilon + 8 && \text{Multiply all parts by 2.} \\
 -\varepsilon + 7 &< 2x - 1 < \varepsilon + 7 && \text{Subtract 1 from all parts to get } 2x - 1 \text{ in the middle.}
 \end{aligned}$$

This inequality is enough justification that $f(x) = 2x - 1$ is within ε units of 7. This completes the proof.

Note: With $\delta = \frac{\varepsilon}{2}$, note that as ε gets closer to 0, so does δ . This is crucial for proving a limit. This is the mathematical version of saying “as x gets closer to a , $f(x)$ gets closer to L ”.

➡ **EXAMPLE** Prove the limit: $\lim_{x \rightarrow 9} (50 - 4x) = 14$

First, find an expression for δ in terms of ε :

$$\begin{aligned}
 |50 - 4x - 14| &< \varepsilon && \text{Start with the inequality.} \\
 |36 - 4x| &< \varepsilon && \text{Simplify the expression.} \\
 -\varepsilon &< 36 - 4x < \varepsilon && |x| < a \text{ means } -a < x < a. \\
 -\varepsilon - 36 &< -4x < \varepsilon - 36 && \text{Subtract 36 from all parts.} \\
 \frac{\varepsilon}{4} + 9 &> x > -\frac{\varepsilon}{4} + 9 && \text{Divide all parts by -4 (note: inequalities change direction).}
 \end{aligned}$$

$$-\frac{\varepsilon}{4} + 9 < x < \frac{\varepsilon}{4} + 9 \quad \text{Rewrite the inequality.}$$

$$-\frac{\varepsilon}{4} < x - 9 < \frac{\varepsilon}{4} \quad \text{Subtract 9 to get } x - 9 \text{ in the middle.}$$

At this point, it appears that $\delta = \frac{\varepsilon}{4}$. Now, reverse the steps.

$$-\frac{\varepsilon}{4} < x - 9 < \frac{\varepsilon}{4} \quad \text{Start with the inequality.}$$

$$-\frac{\varepsilon}{4} + 9 < x < \frac{\varepsilon}{4} + 9 \quad \text{Add 9 to all parts.}$$

$$\varepsilon - 36 > -4x > -\varepsilon - 36 \quad \text{Multiply all parts by } -4 \text{ (inequalities change direction).}$$

$$-\varepsilon - 36 < -4x < \varepsilon - 36 \quad \text{Rewrite the inequality.}$$

$$-\varepsilon + 14 < -4x + 50 < \varepsilon + 14 \quad \text{Add 50 to all parts.}$$

At this point, we see that $f(x)$ is within ε units of 14. This completes the proof.

WATCH

The following video walks you through an example of finding δ to prove a limit for a linear function.

TRY IT

Consider $\lim_{x \rightarrow 3} (6x - 11) = 7$.

[Prove this limit.](#)

+

Repeat the processes you saw in the first example. You should use $\delta = \frac{\varepsilon}{6}$.

SUMMARY

In this lesson, you learned that by using **the formal definition of a limit**, you can establish the true meaning of what it means for a limit to exist, by comparing δ and ε . You also learned that when **proving limits (finding δ in terms of ε)**, it crucial to note that as ε gets closer to 0, δ also gets closer to 0, and is the mathematical expression of “as x gets closer to a , $f(x)$ gets closer to L .”
